

3. Modifying Series and DataFrames

```
main.py > ...
1  import pandas as pd
2  data = {
3      'Name' : ['Alice', 'Bob', 'Charlie'],
4      'Age' : [10, 20, 30],
5      'Score' : [100, 110, 120]
6  }
7  df = pd.DataFrame(data)
8  df.set_index('Name', inplace=True)
9  print(df)
```

PROBLEMS OUTPUT TERMINAL ... Python

```
PS C:\Users\ranga\Desktop\python> python main.py
      Age  Score
Name
Alice    10   100
Bob      20   110
Charlie  30   120
PS C:\Users\ranga\Desktop\python>
```

1. `at` method

`at` is label-based.

Used to access values in a DataFrame and modify them by their labels using `at` method.

```
df.at['Alice', 'Age'] = 50
```

```
10  df.at['Alice', 'Age'] = 50
11  print(df)
```

PROBLEMS OUTPUT TERMINAL ... Python

```
PS C:\Users\ranga\Desktop\python> python main.py
      Age  Score
Name
Alice    50   100
Bob      20   110
Charlie  30   120
PS C:\Users\ranga\Desktop\python>
```

2. `iat` method

`iat` is integer position-based.

Used access values in a DataFrame and modify them by their index using `iat` method.

```
df.iat[1,1] = 0
```

```
10 df.at['Alice', 'Age'] = 50
11 df.iat[1, 1] = 0
12 print(df)
```

PROBLEMS OUTPUT TERMINAL ... Python

```
● PS C:\Users\ranga\Desktop\python> python main.py
      Age  Score
Name
Alice    50   100
Bob      20     0
Charlie  30   120
○ PS C:\Users\ranga\Desktop\python>
```

3. Adding a column

```
df[newColumnName] = [..Values..]
```

```
10 df['Rating'] = [1, 2, 5]
11 print(df)
```

PROBLEMS OUTPUT TERMINAL ... Python

```
● PS C:\Users\ranga\Desktop\python> python main.py
      Age  Score  Rating
Name
Alice    10   100      1
Bob      20   110      2
Charlie  30   120      5
○ PS C:\Users\ranga\Desktop\python>
```

4. Adding rows

First create a new DataFrame with desired rows, then concatenate the original DataFrame and the new one.

Ex: Add a new player called 'David'(index) with age of 20 and 95 scores.

```
10 new_row = pd.DataFrame(  
11     {'Age': [25], 'Score': [95]}, index=['David']  
12 )  
13 df = pd.concat([df, new_row])  
14 print(df)
```

PROBLEMS OUTPUT TERMINAL ... Python + -

● PS C:\Users\ranga\Desktop\python> python main.py

	Age	Score
Alice	10	100
Bob	20	110
Charlie	30	120
David	25	95

○ PS C:\Users\ranga\Desktop\python>

5. drop method

`drop` is used to remove Columns and Rows from a DataFrame.

In the `drop` method, it requires to mention in which axis we need to perform the delete operation.

axis=1 (Indicates Y axis, columns)
axis=0 (Indicates X axis, rows)

Ex: Delete Bob's records.

```
10 df.drop('Bob', axis=0, inplace=True)  
11 print(df)
```

PROBLEMS OUTPUT TERMINAL ... Python

● PS C:\Users\ranga\Desktop\python> python main.py

	Age	Score
Name		
Alice	10	100
Charlie	30	120

○ PS C:\Users\ranga\Desktop\python>

Ex: Delete Age column

```
10 df.drop('Age', axis=1, inplace=True)
11 print(df)
```

PROBLEMS OUTPUT TERMINAL ... Python

```
● PS C:\Users\ranga\Desktop\python> python main.py
      Score
Name
Alice    100
Bob      110
Charlie  120
○ PS C:\Users\ranga\Desktop\python> 
```
